This program was conducted under Contract DAAJ02-70-C-0012 with Kaman Aerospace Corporation.

This report contains the theoretical derivation and the presentation of a methodology for system identification of structures. Computer experiments were run to verify this methodology.

The report has been reviewed by this Directorate and is considered to be technically sound. It is published for the exchange of information and the stimulation of future research.

This program was conducted under the technical management of Mr. Arthur J. Gustafson, Technology Applications Division.

FOREWORD

The work presented in this report was performed by Kaman Aerospace Corporation under Contract DAAJ02-70-C-0012 (Task 1F162204AA4301) for the Eustis Directorate, U. S. Army Air Mobility Research and Development Laboratory, Fort Eustis, Virginia. The program was implemented under the technical direction of Mr. Joseph H. McGarvey of the Reliability and Maintainability Division* and Mr. Arthur J. Gustafson of the Structures Division.** The report is presented in four volumes, each describing a separate phase of the basic theory of structural dynamic testing using impedance techniques.

Volume I presents the results of an analytical and numerical investigation of the practicality of system identification using fewer measurement points than there are degrees of freedom. The parameters in Lagrange's equations of motion, mass, stiffness, and damping for a mathematical model having fewer degrees of freedom than the linear elastic structure it represents may be determined directly from measured mobility data. Volume II describes the method of system identification wherein the necessary impedance data are experimentally determined by applying a force excitation at a single point on the structure. Volume III presents a method of determining the free-body dynamic responses from data obtained on a constrained structure. Volume IV describes a method of obtaining the equations for the combination of measured mobility matrices of a helicopter and its subsystems. The response of the combination of a helicopter and its subsystems is determined from data based on the experimental results of the main system and subsystems separately.

INTRODUCTION

The success of a helicopter structural design is highly dependent on the ability to predict and control the dynamic response of the fuselage and appended components. An effective dynamic analysis of complex systems should yield the response of the primary system and its associated subsystems. It is extremely desirable to analytically predict the complete response of a linear elastic structure due to the addition or alteration of particular components.

This report describes a method whereby the dynamic response of the entire system can be determined from knowledge of the response of the main system and the subsystem separately. The formulation is predicated on the theory of structural dynamic testing using impedance techniques. The analysis requires measured mobility matrices for the basic structure alone and free mobility matrices for the attached component. Therefore, once the mobility matrices for the basic system are measured, they can be continually used in conjunction with the measured free mobilities for the various components connected to the main structure.

It is anticipated, in practice, that the mobility matrix for the basic system would be obtained by the method of Volume II of this report and that the free mobilities for the components would be obtained by the method of Volume III.

Specifically, in the present report the primary system was a 20-degree-of-freedom representation of an actual helicopter, and three types of subsystems were considered. The subsystems studied included a spring-mass system connected at a single point, a rigid inertial mass elastically attached at two points, and a beam elastically connected at three or more points. The method employed simulated test data to represent the required experimental mobility data, and measurement errors were introduced to test the sensitivity of the theory to error.

THEORY

Consider a finite degree of freedom simulation of an actual helicopter. The impedance matrix for the system can be expressed in terms of mobilities

$$\begin{bmatrix} \hat{Z}_{AA} & \hat{Z}_{AB} \\ \hat{Z}_{BA} & \hat{Z}_{BB} \end{bmatrix} = \begin{bmatrix} \hat{Y}_{AA} & \hat{Y}_{AB} \\ \hat{Y}_{BA} & \hat{Y}_{BB} \end{bmatrix}^{-1} \equiv [\hat{Y}]^{-1} \quad (1)$$

The impedance of a subsystem to be attached to the primary system can also be expressed in terms of mobilities

$$\begin{bmatrix} 0 & 0 \\ 0 & \hat{Z}_B \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & [\hat{Y}_B]^{-1} \end{bmatrix} \equiv [\hat{Y}_B]^{-1} \quad (2)$$

The mobility of the combined system is defined as the inverse of the impedance

$$[Y] \equiv \left(\begin{bmatrix} \hat{Z}_{AA} & \hat{Z}_{AB} \\ \hat{Z}_{BA} & \hat{Z}_{PB} \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & [\hat{Y}_B]^{-1} \end{bmatrix} \right)^{-1} \quad (3)$$

The product of the impedance matrix and the mobility matrix is the unit matrix

$$[Z][Y] = ([\hat{Y}]^{-1} + [\hat{Y}_B]^{-1}) [Y] = [I] \quad (4)$$

Multiplying both sides of Equation (4) by $[\hat{Y}]$ and solving for $[Y]$ yields

$$[Y] = ([I] + [\hat{Y}][\hat{Y}_B]^{-1})^{-1} [\hat{Y}] \quad (5)$$

Substituting the actual matrices into the matrix Equation (5),

$$\begin{bmatrix} [Y_{AA}] & [Y_{AB}] \\ [Y_{BA}] & [Y_{BB}] \end{bmatrix} = \left(\begin{bmatrix} [I] & 0 \\ 0 & [I] \end{bmatrix} + \begin{bmatrix} [\hat{Y}_{AA}] & [\hat{Y}_{AB}] \\ [\hat{Y}_{BA}] & [\hat{Y}_{BB}] \end{bmatrix} \begin{bmatrix} 0 & 0 \\ 0 & [Y_B]^{-1} \end{bmatrix} \right)^{-1} \begin{bmatrix} [\hat{Y}_{AA}] & [\hat{Y}_{AB}] \\ [\hat{Y}_{BA}] & [\hat{Y}_{BB}] \end{bmatrix} \quad (6)$$

Performing the indicated operations within the matrix inverse results in

$$\begin{bmatrix} [Y_{AA}] & [Y_{AB}] \\ [Y_{BA}] & [Y_{BB}] \end{bmatrix} = \begin{bmatrix} [I] & [\hat{Y}_{AB}][\hat{Y}_B]^{-1} \\ 0 & [I] + [\hat{Y}_{BB}][Y_B]^{-1} \end{bmatrix}^{-1} \begin{bmatrix} [\hat{Y}_{AA}] & [\hat{Y}_{AB}] \\ [\hat{Y}_{BA}] & [\hat{Y}_{BB}] \end{bmatrix} \equiv [X][\hat{Y}] \quad (7)$$

To facilitate solution of the matrix Equation (7), the inverse of the matrix on the right side of the equation must be evaluated. Let

$$\begin{bmatrix} [X_{11}] & [X_{12}] \\ [X_{21}] & [X_{22}] \end{bmatrix} \begin{bmatrix} [I] & [Y_{AB}][Y_B]^{-1} \\ 0 & [I] + [\hat{Y}_{BB}][Y_B]^{-1} \end{bmatrix} = \begin{bmatrix} [I] & 0 \\ 0 & [I] \end{bmatrix} \quad (8)$$

Therefore

$$\begin{aligned} [X_{11}] &= [I], \quad [\hat{Y}_{AB}][Y_B]^{-1} + [X_{12}]([I] + \hat{Y}_{BB}[Y_B]^{-1}) = 0 \\ X_{21} &= 0, \quad [X_{22}]([I] + [\hat{Y}_{BB}][Y_B]^{-1}) = [I] \end{aligned} \quad (9)$$

Solving for the elements of the X matrix yields

$$\begin{bmatrix} [X_{11}] & [X_{12}] \\ [X_{21}] & [X_{22}] \end{bmatrix} = \begin{bmatrix} [I] & -[\hat{Y}_{AB}][Y_B]^{-1} [I] + [\hat{Y}_{BB}]^{-1} \\ 0 & [I] + [\hat{Y}_{BB}][Y_B]^{-1} \end{bmatrix}^{-1} \quad (10)$$

Substituting the X matrix as expressed in Equation (10) into Equation (7) and expanding gives

$$\begin{bmatrix} \begin{bmatrix} Y_{AA} \\ Y_{BA} \end{bmatrix} \begin{bmatrix} Y_{AB} \\ Y_{BB} \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} \hat{Y}_{AA} \\ \hat{Y}_{BA} \end{bmatrix} \begin{bmatrix} \hat{Y}_{AB} \\ \hat{Y}_{BB} \end{bmatrix} \left(\begin{bmatrix} Y_B \\ Y_{BB} \end{bmatrix} \right)^{-1} \begin{bmatrix} \hat{Y}_{BA} \\ \hat{Y}_{BB} \end{bmatrix} \begin{bmatrix} \hat{Y}_{AB} \\ \hat{Y}_{BB} \end{bmatrix} \left(\begin{bmatrix} Y_B \\ Y_{BB} \end{bmatrix} \right)^{-1} \begin{bmatrix} \hat{Y}_{BB} \end{bmatrix} \\ \left(\begin{bmatrix} I \\ Y_{BB} \end{bmatrix} \begin{bmatrix} Y_B \\ Y_{BB} \end{bmatrix} \right)^{-1} \begin{bmatrix} \hat{Y}_{BA} \\ \hat{Y}_{BB} \end{bmatrix} \left(\begin{bmatrix} I \\ Y_{BB} \end{bmatrix} \begin{bmatrix} Y_B \\ Y_{BB} \end{bmatrix} \right)^{-1} \begin{bmatrix} \hat{Y}_{BB} \end{bmatrix} \end{bmatrix} \quad (11)$$

Equation (11) can be simplified to

$$\begin{bmatrix} \begin{bmatrix} Y_{AA} \\ Y_{BA} \end{bmatrix} \begin{bmatrix} Y_{AB} \\ Y_{BB} \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} \hat{Y}_{AA} \\ \hat{Y}_{BA} \end{bmatrix} \begin{bmatrix} \hat{Y}_{AB} \\ \hat{Y}_{BB} \end{bmatrix} \\ 0 \quad 0 \end{bmatrix} - \begin{bmatrix} \begin{bmatrix} \hat{Y}_{AB} \\ \hat{Y}_{BB} \end{bmatrix} \begin{bmatrix} \hat{Y}_{AB} \\ \hat{Y}_{BB} \end{bmatrix} \\ \begin{bmatrix} -Y_B \\ -Y_B \end{bmatrix} \begin{bmatrix} -Y_B \\ -Y_B \end{bmatrix} \end{bmatrix} \begin{bmatrix} \left(\begin{bmatrix} Y_B \\ Y_{BB} \end{bmatrix} \right)^{-1} \begin{bmatrix} \hat{Y}_{BA} \\ \hat{Y}_{BB} \end{bmatrix} \quad 0 \\ 0 \quad \left(\begin{bmatrix} Y_B \\ Y_{BB} \end{bmatrix} \right)^{-1} \begin{bmatrix} \hat{Y}_{BB} \end{bmatrix} \end{bmatrix} \quad (12)$$

Equation (12) yields the response of the complete system for force excitation at each position on the main system including the interface points. Since the force excitation on a helicopter is usually applied at one particular point, Equation (12) can be reduced, yielding the complete structural response for forcing at a single point on the structure. Thus, Equation (12) reduces to a column of mobilities for force excitation applied at position j of the structure

$$\begin{Bmatrix} Y_{AA} \\ Y_{BA} \end{Bmatrix}_j = \begin{Bmatrix} Y_{AA} \\ 0 \end{Bmatrix}_j - \begin{bmatrix} \hat{Y}_{AB} \\ -Y_B \end{bmatrix} \left[\begin{bmatrix} Y_B \\ Y_{BB} \end{bmatrix} \right]^{-1} \begin{Bmatrix} \hat{Y}_{BA} \end{Bmatrix}_j \quad (13)$$

where $\begin{bmatrix} Y_{AA} \\ Y_{BA} \end{bmatrix}$ represents the dynamic response of each position on the primary system excluding the interface points and $\begin{bmatrix} \hat{Y}_{AB} \\ \hat{Y}_{BB} \end{bmatrix}$ describes the response of the attachment points.

It is possible to obtain the dynamic response for the complete system utilizing the modal matrix of the points of interest on the primary structure exclusive of attachment points, the modal matrix of the interface points and the complex modal mobility of the primary system and the free mobility of the

appendel subsystem. These parameters can be obtained employing the techniques described in References 1 and 2. Following the method of Reference 2, the mobility of the main system exclusive of the subsystem connection points is given by

$$[Y_{AB}] = [\hat{\phi}_A] [\hat{Y}^*] [\hat{\phi}_B]^T \quad (14)$$

where the number of rows of the matrix $[\hat{\phi}_A]$ corresponds to the number of points of interest on the main system, exclusive of the subsystem attachment points, and the number of columns corresponds to the number of moles and is equal to the total number of points of interest on the primary system including the interface points. Matrix $[\hat{\phi}_B]$ has the same number of columns as the number of connection points between the two systems and the identical number of columns as matrix $[\hat{\phi}_A]$. The mobility of the subsystem attachment point is $[\hat{\phi}_A]$.

$$[\hat{Y}_{BB}] = [\hat{\phi}_B] [\hat{Y}^*] [\hat{\phi}_B]^T \quad (15)$$

If Equations (14) and (15) are substituted in Equation (13), the result is

$$\begin{aligned} \begin{Bmatrix} Y_{AA} \\ Y_{BA} \end{Bmatrix}_j &= \begin{Bmatrix} \hat{Y}_{AA} \\ 0 \end{Bmatrix}_j - \begin{bmatrix} [\hat{\phi}_A] [\hat{Y}^*] [\hat{\phi}_B]^T \\ - [Y_B] \end{bmatrix} \begin{bmatrix} [Y_B] \end{bmatrix} \\ &+ [\hat{\phi}_B] [\hat{Y}^*] [\hat{\phi}_B]^T^{-1} \begin{Bmatrix} \hat{Y}_{BA} \end{Bmatrix}_j \end{aligned} \quad (16)$$

ERROR ANALYSIS

Measurements of the complex mobilities will be subject to experimental errors of various types, including errors in equipment calibration, errors resulting from equipment incompatibility, errors due to extraneous signals and errors due to random noise.

Generally, all errors can be classified as either random or bias. The random errors are equally likely to be positive or negative, whereas the bias errors are systematic and in one direction only. In the present study,

both types of measurement error have been included. The simulated experimental data were polluted with measurement errors of +5 percent random and 5 percent bias or both the real and imaginary components of displacement mobility.

As indicated in Reference 3, there is no definitive probability distribution for errors of each type in impedance testing practice. In the present analysis, a random number generator was utilized with a resultant uniform distribution of random error. The rectangular distribution of accidental type error between the selected limits is very conservative compared to the usual definition of the limits at three standard deviations from the mean of a normal distribution.

COMPUTER SIMULATION RESULTS

A computer study to determine the response of the combination of a helicopter and its subsystems based on the simulated test results of the individual system and subsystems can be extremely useful in the development cycle of a helicopter. In the present analysis, a mathematical model was established to provide for a wide range of cross-coupling effects to simulate diverse subsystems. The helicopter, or main system, was represented by a 20-degree-of-freedom mathematical model. Table I presents a lumped mass description of the aforementioned specimen which was used to generate the simulated experimental data. Three types of subsystems were incorporated in the study, represented as a spring-mass system elastically connected at one point, a rigid inertial mass elastically connected at two points and a beam elastically connected at three or more points. Figure 1 shows the aforementioned subsystems.

Figures 2 and 3 present the real and imaginary displacement mobility frequency response for the main system-subsystem interface point for a spring-mass subsystem. The force excitation was applied at Station 6, the hub station, and the response was measured at Station 3, the general area of the pilot seat, and coincident with the subsystem attachment point. Data are presented for conditions of zero experimental error and for simulated experimental displacement mobility data recorded with a random error of +5 percent and a bias error of +5 percent. For the cases involving error, the random displacement mobility error was computed using a uniformly distributed probability density function. This error was applied to both the real and imaginary components of the main and subsystem displacement mobility data. As can be observed from Figures 2 and 3, the method is extremely insensitive to the measurement error as applied herein. Figures 4 and 5 show the same type data as given in the previous figures except that the subsystem investigated was a rigid inertial mass elastically attached to the main structure at two points. The interface points in this situation are located at Stations 1 and 2 of the main system. Again, the frequency response of the displacement mobility, both real and imaginary, is effectively invariant with error for the error level incorporated. Figures 6 and 7 present the same type results for the beam subsystem elastically connected at three points. The attachment points in this instance are at Stations 1, 2, and 3 of the main system. The data substantiate the previous observations of the relative insensitivity of the method to error.

Figure 6. Real Displacement Mobility Frequency Response; Combination of Main System and Beam Subsystem.

Figure 7. Imaginary Displacement Mobility Frequency Response; Combination of Main System and Beam Subsystem.

The effect of a spring-mass subsystem on the response of the 20-degree-of-freedom mathematical representation of the helicopter is shown in Figure 8. A sinusoidal force excitation was applied at the hub station, and the real displacement mobility is given for the basic system alone and for the main system with subsystem attached at Station 3, the pilot seat location. The forcing frequency was 9.2 Hertz, which is the calculated natural frequency of the spring-mass subsystem alone. As would be expected, the response of the total system is characterized by a nodal point at the interface station. The effect of error is also indicated on the figure. The dispersion of the results using the various random error seeds is within an acceptable level. Figure 9 presents similar data as Figure 8 except that the forcing frequency is 20 Hertz. The disturbing frequency is separated enough from the subsystem resonant frequency that there is essentially no difference in the system response with or without subsystem attached. Figures 10 and 11 illustrate the influence of the rigid inertial mass subsystem on the response of the combination of the basic helicopter representation and the appended subsystem. The forcing frequencies used represent the approximate natural frequencies of the subsystem alone. The effect of error can be observed from the figures, and the insensitivity of the analysis to measurement error is again visible. The response of the configuration, consisting of the main system and a beam elastically connected at three points on the main structure, is represented in Figure 12 for an excitation frequency of 10 Hertz and in Figure 13 for a forcing frequency of 30 Hertz. The figures also yield the effect of measurement error on the system displacement mobility response.

The results shown represent a small number of the computer simulation experiments actually conducted. For each of the subsystem configurations considered, the location of the attachment points along the main system could be varied as long as compatibility between the systems was maintained. The flexibility of the method presented in this report in determining the response of the combination of a helicopter and its subsystems based on test results of the individual system and subsystems provides a means of modifying subsystem characteristics, interface locations and connection effects. A wide range of cross-coupling effects to simulate diverse subsystems can be analyzed based on the measured mobilities of the individual subsystems, since the mobility data of the main system, once measured, remain constant.

A digital computer program listing in FORTRAN IV language and a description of the program input cards are given in the appendix.

CONCLUSIONS

1. The response of the combination of a helicopter and its subsystems can be determined based on the test results of the individual system and subsystems.
2. The method is insensitive to measurement error using simulated test data subjected to errors that are within the state of the measurement art.
3. The method can be used to study a wide range of cross-coupling effects to simulate diverse subsystems.
4. At a specific excitation frequency, once the mobility data for the main system are measured, they remain constant; thus, only the measured mobilities of the individual subsystems need be considered.
5. The method provides an expedient means of modifying the subsystems appended to a helicopter at a development stage of the system.
6. The method is amenable to experimental implementation and is numerically sound.

APPENDIX
COMPUTER PROGRAM DESCRIPTION

A digital program was prepared for determining the response of the combination of a helicopter and its subsystems based on the test results of the individual system and subsystems. The program was written for the IBM 360/40 disk operating system using FORTRAN IV language. A flow chart depicting the program logic is shown in Figure 14. A description of the input cards and a program source listing are presented in this appendix.

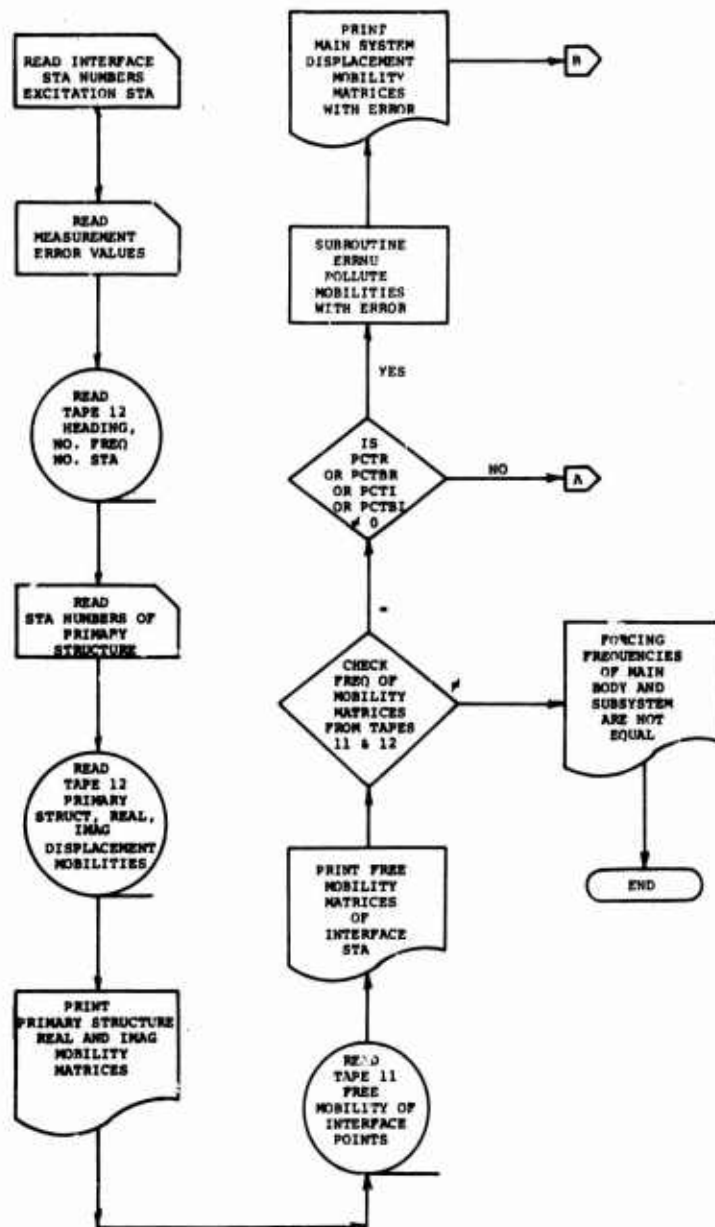

Figure 14. Computer Program Flow Chart.

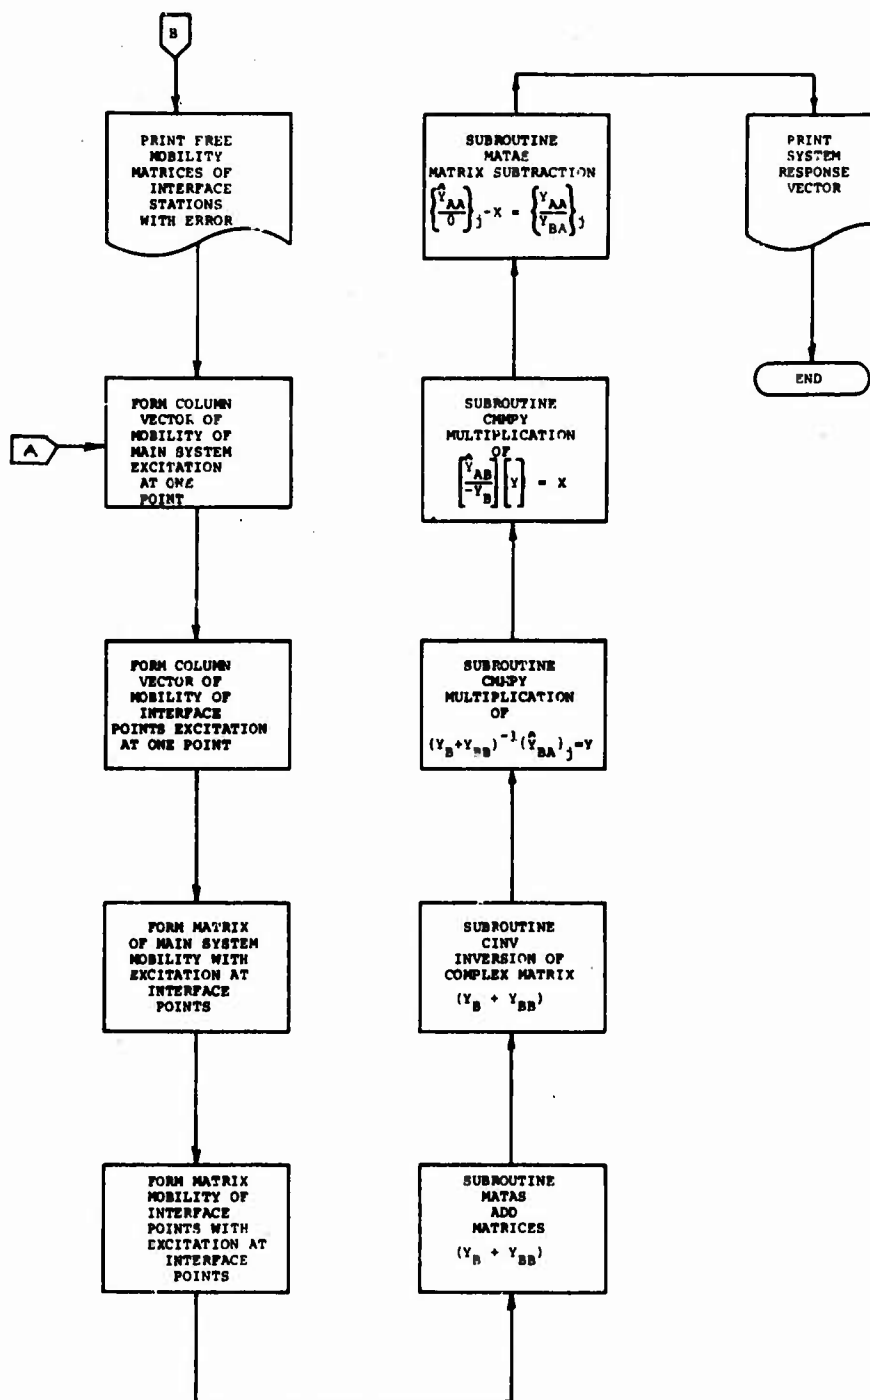

Figure 14 - Concluded.

DESCRIPTION OF INPUT CARDS

Note: All integer variables must be right justified with no decimal point.

Tape, Card Reader and Printer Assignments

- 1 Card Reader
- 3 Printer
- 11 Contains free displacement mobility matrices for subsystem connection points.
- 12 Contains displacement mobility matrices for primary system.

All input data must be in the following units:

Mass - $\text{lb-sec}^2/\text{in.}$

Stiffness - lb/in.

Frequencies - Hz

PROGRAM COMSYSA
COMPONENT SYNTHESIS

Card(s) 1	Columns 1-10	M	Number of interface points (Number of attachment points between subsystem and primary system (FORMAT I10)).
		MS	Interface points, station numbers. 10 columns per value (Maximum 10 values). (FORMAT 8I10).
		NCØL	Primary system station number at which forcing function is applied (FORMAT I10).
Card 2	1-10	PCTR	Random error applied to real mobility. Uniform between - and + PCTR* ELEMENT displacement.
	11-20	PCTBR	Bias error applied to real mobility. PCTBR* ELEMENT displacement.
	21-30	PCTI	Same as PCTR except applied to imaginary displacement mobility.
	31-40	PCTBI	Same as PCTBR except applied to imaginary displacement mobility.
	41-50	IZ	Random error seed, used in generation of error.
Card(s) 3	1-10	KEEP	Stations to be used in primary system. w columns per value, 8 values per card (FORMAT 8I10).
